Informed consent — hair transplant surgery (FUE)

Please read carefully. Ask the doctor about anything that is unclear before signing.

Patient: Amit Joshi, 37 years

Procedure: Follicular unit extraction (FUE), approx. 2,800 grafts

Surgeon: Dr. Bhushan Patil

I understand that hair transplantation is a minor surgical procedure performed under local anaesthesia. Follicular units are removed from the donor area (back and sides of the scalp) and implanted in the thinning areas.

Risks and possible complications

- Pain, swelling of the forehead and eyes for a few days, bleeding and infection.
- Temporary numbness of the scalp; shock loss of existing hair in the recipient area.
- Folliculitis, cysts, visible scarring in the donor area, or poor graft survival.
- Allergic reaction to local anaesthetic (lidocaine) or other medicines.
- Further hair loss in untreated areas may continue; more sessions may be needed.

Expected outcome

Transplanted hair usually sheds in 2–4 weeks and starts to regrow at 3–4 months. Most of the result is visible at 8–12 months. The final density depends on donor quality, graft survival and my own healing; no specific result is guaranteed.

I have disclosed my allergies, medical conditions and all medicines and supplements, including blood thinners. I agree to follow the pre- and post-operative instructions.
